#### PREFACE

This species profile is one of a series on coastal aquatic organisms, principally fish, of sport, commercial, or ecological importance. The profiles are designed to provide coastal managers, engineers, and biologists with a brief comprehensive sketch of the biological characteristics and environmental requirements of the species and to describe how populations of the species may be expected to react to environmental changes caused by coastal development. Each profile has sections on taxonomy, life history, ecological role, environmental requirements, and economic importance, if applicable. A three-ring binder is used for this series so that new profiles can be added as they are prepared. This project is jointly planned and financed by the U.S. Army Corps of Engineers and the U.S. Fish and Wildlife Service.

Suggestions or questions regarding this report should be directed to one of the following addresses.

#### **CHUM SALMON**

#### NOMENCLATURE/TAXONOMY/RANGE

Scientific name Uncorhynchus	keta
(Walbaum 1792) (Figure 1)	
Preferred common nameChum sal	l non
Other common namesDog salmon, f	fall
salmon	
Class Osteichth	yes
Order Sal moni for	nes
FamilySalmon	idae

Geographic range: Chum sal non have the widest distribution of the Pacific ranging from southern sal mon, California (Hallock and Fry 1967) northward through Alaska, arctic shore of Alaska, USSR, Japan, and Korea (Bakkala 1970; Hart 1973). The major rivers of the Pacific Northwest that support chum salmon runs are shown in Figure 2. Centers of abundance for chum salnon are southeastern Alaska and **Prince** William Sound in British Columbia (Atkinson et al. 1967).

#### **MORPHOLOGY/IDENTIFICATION** AIDS

Dorsal fin 10-13 rays; adipose fin smll, slender, fleshy; caudal forked; anal fin 13-17 rays; pectorals 16 rays; pelvics 10 rays and abdominal location, each with a free-tipped fleshy appendage above its insertion. Gill rakers on first arch 18-30. Body elongate and moderately compressed (Hart 1973).

Recognizable by the absence of large black spots on the body and fins, and by the slender caudal peduncle; adult chum salmon are unique in having white tips on pelvic and anal fins, which distinguish them from sockeye salmon. Maturing fish have a series of dark bars and red coloring on sides, and some have gray blotches. Juvenile parr marks appear as slender bars, scarcely extending below lateral lines; have green irridescence on back (Hart 1973).

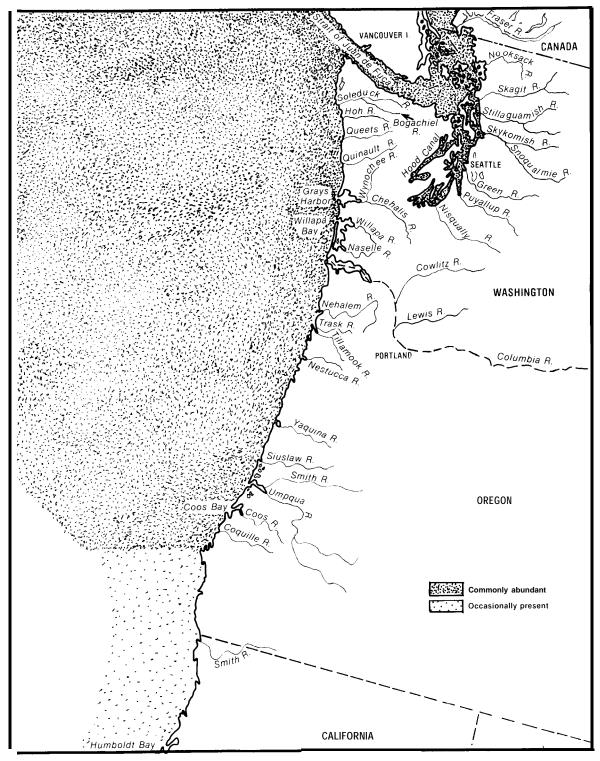

Figure 2. Major rivers and coastal areas supporting chum salmon in the Pacific Northwest.

#### REASON FOR INCLUSION IN SERIES

chum sal non supports a valuable commercial fishery along the coast from Washington to Al aska. This fish is the main income producer for villagers in nanv Al aska. southwestern It occupies ecological niches in both marine and estuarine waters and is important as both a predator and prey species at various life stages.

#### LIFE HISTORY

#### Spawni ng

Chum salmon are anadromous like North Aneri can species of other sal non. but ti ne the spent freshwater is brief and primarily for reproduction (Bakkal a 1970: 1981). Chum salmon migrate to the estuaries during their first spring or summer of life and, like pink salmon, Oncorhynchus gorbuscha, spend minimal time rearing in freshwater. respect, they are considerably unlike merka, coho, Oncorhynchus sockeve. Oncorhynchus kisutch, and chi nook sal non. **Oncorhynchus** tshawtscha, spend longer tines freshwater. Adult chum salmon live in the offshore marine or estuarine environnents.

Like all species of Oncorhynchus, the chum salmon return to the stream in which they hatched, and then die after spawning. Chum sal non are the last of the Pacific salmon to return to their natal streams (Washington State Department of Fisheries 1959; Bakkala 1970), usually leaving the marine waters in summer and late fall to begin their upstream migration. However, in Puget Sound, adult chum salmon enter freshwater as late as Chum sal non enter nay freshwater to spawn as 3-, 4-, or 5- year- old fish (Beacham 1984). Groups of fish that enter the rivers early in Southern British Columbia have higher proportions of older fish

(4- and 5-year-olds) than those that enter the streams later (Beacham 1984). Most chum salmon spawn above the saltwater zone but within 200 km of the sea, although some chum salmon have been reported to migrate up to 322 km upstream to spawn (Hart 1973).

Most rivers have only a summer and fall run of spawning chum salmon. However, in Puget Sound streams, there are three distinct chum salnon runs: from mid-August October: nornal from **November** through December: and late January through March (J. Anes, 1984, **Washington** State Department of Fisheries [WDF]. Ol vmni a: pers. comm.). Adult chum salnon do not feed during the upstream migration generally travel about 20 km per day (Hart 1973). Mattson et al. (1964) reported the time spent by adults in freshwater (time of stream entry to death) to be 11 to 18 days. However, the freshwater life of adult chum that spawn in large systems is sometimes twice that long (J. Anes. 1984. WDF: pers. comm.). In Southern British Columbia, the average size of chum salnon that spawned in small streams was smaller than the average of those that spawned in large rivers (Beacham 1984).

The female chum salmon chooses a nest site on the basis of gravel substrate (Schroder and Duker 1979). The female chum salmon excavates the redd in gravel by turning to one side and rapidly flexing her body, creating water current and removing gravel with the caudal fin. After the depression is complete, the female and dominant male enter the redd and simultaneously extrude eggs and milt. Not all eggs are deposited at one time, as miltiple egg pockets are made. (1975)Grott descri bed female chum salmon as the dominant member of the spawning pair in the sense that the activity of the male occurs in response to the quivering and readying of the spawning area by the female.

The area of chum salmon redds ranges from 0.3 to 4.5 m<sup>2</sup> and averages about  $2.3 \text{ m}^2$  (Burner 1951). It has been suggested that a spawning pair may require a total area of 9.2 m<sup>2</sup> (Burner 1951). However, since chum salnon tend to spawn in groups, this large additional amount of inter-redd spacing (approximately 7.0  $\mbox{\em m}^2)$  is probably unnecessary and a realistic optimum is closer to 2.0 m<sup>2</sup> per female (J. Anes, pers. comm.). Superinposition of redds by later spawners may remove previously deposited eggs from the gravel. In areas of high spawning density, McNeil (1962) reported that up to 50% of the total egg losses were attributed to subsequent displacement. Thorenstein (1965) found that at densities of 45 females per  $m^2$ , as many <sub>eggs</sub> were dislodged as were deposi ted.

#### Fecundity, Eggs, and Alevins

Female chum salmon produce from 900 to 8,000 eggs, with the fecundity of samples from North America and Asia averaging 2,000 to 3,000 eggs (Bakkala Watanabe (1955) reported that fecundity and size of eggs increase with length of the spawning female. Several investigators (Hunter 1959; McNeil 1962) have proposed that nost nortality that occurs between egg fertilization and the early fry stage occurs while eggs are incubating. Factors which influence egg survival include superimposition of redds by later spawners, sedimentation, oxygen, predators, light, freezing, and erosion of streambeds caused by flooding and drought (Bakkala 1970). Drought can have two effects: (1) eggs or alevins may be killed through lack of streamflow, which can result in insufficient di ssol ved oxvgen. siltation, or desiccation; and (2) spawners may be forced to use inappropriate spawning sites because of low flows.

Egg density did not affect fry survival but altered the time of emergence, which in turn influenced

fry condition, which is measured by length- to- weight relationship (Kapuscinski and Lannan 1983). survival rate of eggs to fry is typically less than 10% (Hale 1981). Egg survival from fertilization to hatching was highest for eggs from small females and lowest for those females at from large vari ous temperatures (Beacham and Chum salmon eggs incubate in 1985). the gravel for 50 to 130 days (Hale 1981). After hatching, the larvae with yolk sacs attached (alevins) remain in the gravel. The yolk sacs are fully absorbed 30 to 50 days later. Alevins produced by larger females had more yolk reserves and more body tissue at hatching than those produced by smaller females (Beacham and Murray 1985). Alevins energe from the gravel as fry in the spring.

#### fry and Snolts

Most chum salmon fry begin their downstream migration to the ocean soon energence. In general, increased fry emergence results from increased deposition of eggs; the more spawning fish, the more progeny that are produced up to a limit of about 330 fry per  $\mathbb{M}^2$ . Some fry remain in freshwater for several especially those that are hundreds of miles from the ocean. outnigration occurs mainly at night in the spring (Hale 1981). A small percentage of juvenile chum salmon rear entirely in freshwater (J. Anes, pers. comm.). Chum salnon 80-mm long occur in the streams during the summer nonths, but they typically enter saltwater by the end of the summer. The work of Iwata and Konatsu (1984) indicated that it was important that some rearing take place in the estuary because chum fry reared exclusively in freshwater may be at a distinct disadvantage when they enter seawater. researchers have suggested that estuaries are important nursery areas for chum salmon (Mason 1974; Sinenstad and Kenny 1978; Healey 1980;

Congleton et al. 1982; Levy and Northcote 1982; Bax 1983b; Iwata and Konatsu 1984).

In the State of Washington, Hood Canal provides an important passageway and nursery area for chum salnon, accounting for about 25% of Washington State's adult chum salnon returns (Fiscus 1969; Morrill 1974; Bax et al. The period of early marine residence, the estuarine-to-oceanic transition (at <55 mm total length), is considered the most critical phase in the life history of the chum salmon and the one which ultimately determines the number of adult returns (Mathews and Senn 1975; Fraser et al. 1978; Bax 1983a,b). After the salmon reach a size greater than 55 mm, they move into the offshore marine neritic environment. It appears that the estuarine environment provides a refuge from predation (Parker 1971) an abundance of preferred epibenthic prey (Feller and Kaczynski 1975) until juvenile chum salmon reach a length that is more advantageous for oceanic survival.

The fry enter the estuaries in schools, usually by June, and remain until mid- or late summer. The young chum salmon feed mainly in the estuaries, though some go back into freshwater areas with the changing tides to feed (Mason 1974). By mid-August to September, all juveniles at lengths of 150-225 mm have left the river estuaries for the offshore ocean environment (Hale 1981). Migration of chum fry to saltwater is obligatory within the first summer after hatching die if kept in they will freshwater for 7 to 8 months after hatching (Houston 1961). **Prolonged** rearing in freshwater and extended rearing close to their point of saltwater entry may cause higher nortality of the juvenile chum salmon than would otherwise be expected (Iwata et al. 1982; Bax 1983a).

After leaving the estuarine environment, immature chum salnon

wi del y distributed at sea throughout the North Pacific Ocean to a southern limit of about  $40^{\circ}$  to  $44^{\circ}$  N Large numbers of immature latitude. age 2 chum salnon occur in Puget Sound during the summer and fall months, but no immature age 3 chum have been observed. which would suggest that some chum salmon spend a year or more in Puget Sound and that all fish eventually enter the Pacific Ocean (J. Ames, pers. comm.). In the Gulf of Alaska, chum salmon were found in the upper 61 m of the water column from May to July, approaching the surface at night (Manzer 1956). Main food items in the offshore area consist of invertebrates and fish (Bakkala 1970).

Mature salmon range from age 2 to age 7, although age 6 and age 7 fish are not commonly observed (Bakkala 1970; Hale 1981). Most chum salmon mature at age 4 to age 5 in Alaska and British Columbia and at age 3 to age 4 in Washington and Oregon (J. Anes, pers. comm.). Adults range from 45 to 96 cm in fork length and from 0.8 to 13.4 kg in weight, with the mean size for sexually mature fish being 60 to 75 cm and 4.0 to 7.0 kg (Bakkala 1970; Merrell 1970; Morrow 1980). Maturing adults begin their migration to natal streams in the last few months of Little time is spent in their lives. nearshore coastal waters by adults they begin their upstream before migration to the spawning grounds (Hale 1981). Most upstream migrants have spent 2 to 4 years at sea. Brannon (1982) described salmon spawning migrations toward their rivers as being initiated and dependent primarily upon odor. Temperature and river flow were proximal influences on locomotion and confort, but did not play any role in home stream recognition (Brannon 1982).

#### **GROWTH CHARACTERISTICS**

The use of scale annulus formation to determine age in chum

salmon was discussed by LaLanne and Safsten (1969). The length and weight of chum salmon at hatching are about 22 mm and about 0.16 g respectively, while after absorption of the yolk sac they are 27 to 32 mm long and weigh about 0.20 g (Bakkala 1970). In experimental | situations, the growth rate of juvenile chum salmon was dependent on the concentration of food (LeBrasseur **1969**). Ricker **(1964)** summarized the growth of chum salmon stocks from various areas along the Pacific Coast from scale analysis and noted that the percent weight increase declined each year as the fish grew older. Beacham (1984) noted that for each age group of returning adult chum salmon, fish from large rivers were larger in size than those from small streams.

#### THE FISHERY

The chum sal non is an important component of the commercial fishery from Washington northward along the Pacific Coast (Figure 2). The major chum sal non fishery is centered in Southeast Alaska and British Columbia (Figure 3). The total commercial sal non catch north of Bristol Bay, Alaska, consists primarily of chum sal non and provides income for many villagers in western Alaska (Hale 1981).

Chum salnon stocks in Washington State increased greatly in the mid-1980's because of a massive enhancenent program Hood Canal rivers that flow into it were managed principally for the production of chum salmon (Bax et al. 1979: Whitmus and Olsen 1979). Chum salnon production in Washington State has increased, in part due to hatchery production and in part due to increased management effort on this species. Chum sal non landings in relation to total landings for all salmon species in Washington State are shown in Table 1.

The 1978 and 1980 connercial harvests averaged 1,150,000 fish,

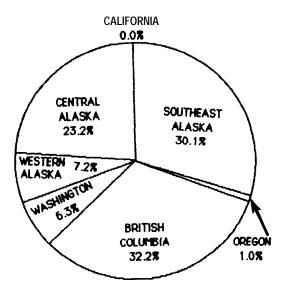

Figure 3. Average percentages of the Pacific Coast State and Province commercial harvest of chum salmon, 1920-79 (modification of data from Pacific Marine Fisheries Commission 1983).

which is equivalent to the harvests in Washington State during the 1930's and 1940's (J. Anes, pers. Native runs also have benecomm.). fited from the hatchery enhancement, and total chum salmon returns to Puget Sound now include a major portion of native stocks along with the hatchery returns (Table 2). **Odd-numbered** years are historically low-harvest years for chum salmon (Tables 1 and 2). Harvest rates determined for the terminal area fishery are based on preseason run **forecasts** (mi nus escapement goals), and updates of the run size throughout the season (Washington State Department of Fisheries 1983).

Although not a prime target for sport fishermen in the Pacific Northwest (Haw and Buckley 1973), chum salmon are caught incidently by anglers fishing for coho and chinook salmon. Chum salmon sport fisheries in Washington State are localized primarily in southern Puget Sound. Interest in this species as a recreational

fish has been growing each year (J. Anes, pers. comm.).

#### ECOLOGICAL ROLE

Because most chum sal non begin to migrate to marine waters as juveniles, they feed very little in freshwater (LeBrasseur and Parker 1964). Bakkala (1970) described benthic organisms, chiefly aquatic insects, as their primary food in freshwater. During their estuarine existence, chum sal non are size-selective predators that preferentially feed on epibenthic organisms: harpacticoid copepods,

gammaridean amphipods, cumaceans, and mysids (Gerke and Kaczynski 1972; Feller and Kaczynski 1975; Simenstad and Kenny 1978). Harpacticoid Copepods were found to be numerically dominant as food items of chum salmon fry, while a single prey item, the copepod Harpacticus unirevais, often composed more than 80% of the diet, even though it was comparatively rare in the epibenthic fauna (Gerke and Kaczynski 1972; Healey 1979).

After reaching a length greater than 55 mm, juvenile chum salmon migrate to the offshore neritic zone and feed on larger planktonic organisms such as calanoid copepods, hyperiid anphipods, larvaceans, and fish larvae (Sinenstad and Kenny 1978). Peterson (1982) found that an euphau-Thysanoessa spinifera, hyperiid amphipod, Hyperoche medusarum, were the primary food items of juvenile chum salmon off the coast of Juvenile chum salmon off the Oregon. southern British Col unbi a coast shi fted from crustaceans and other invertebrates to fish as they grew larger than 95 mm (Shepard that LeBrasseur (1966) suggested feeding habits and differences in stonach contents of adult chum salmon in offshore areas were based on availability rather than on preferences for certain kinds of organisms. salnon digest food faster than any

other species of salmon and feed extensively on readily digested organisms, thereby making stomach analysis difficult (Bakkala 1970).

Predation on chum salmon fry in the freshwater during their downstream migration is a major source of nortality (Hale 1981), where common predators are cutthroat trout (Salmo clarki), rainbow trout (Salmo gairdneri), Dolly Varden (Salvelinus malna), coho salnon snolts (Oncorhynchus kisutch), sculpins (Cottus spp.), belted kingfishers (Ceryle alcyon), and mergansers (Mergus sp.). Predation on juvenile chum salmon in the estuaries by coho salmon smolts, Dolly Varden, and fish-eating birds is possibly correlated with juvenile chum salmon hatchery release time (Shepard Allen (1974) reported pigeon guillenots (Cepphus columba), marbled murrelets (Brachyranphus marnoratus), and pelagic cornorants (Phalacrocorax pelagicus) were in close association with juvenile chum salmon in a British Columbia estuary. Cardwell and Fresh (1979) concluded that bird predation on salmon fry was low in Puget Sound. However, available evidence indicates that the nortality of juvenile chum salmon during early life at sea is high and is probably size dependent (Parker 1971; Healey 1982). The most important predators of chum salmon in the offshore marine environment inmarine birds. killer whales orca), sea lions (Eunetopias (Orci nus jubatus and Zalophus californianus), harbor seals (Phoca vitulina), and various pelagic fishes and sharks (Bakkala 1970).

Other Pacific salmon are the principal competitors of chum salmon. The various species intermingle in the marine environment, estuaries, and on the spawning grounds. Parker (1971) noted that juvenile coho salmon preyed heavily on juvenile chum salmon. However, Hargreaves and LeBrasseur (1985) found that yearling coho salmon prey selectively on pink salmon, even when chum salmon are both significantly

smaller and more abundant than pink However, pink salmon fry, sal non. although abundant in the tidal channels in even-numbered years, normally do not stay in estuaries at the same times that chum salmon fry are abundant there, because the pink salmon migrate quickly through the marsh and into the sea (Levy and Northcote The two species of salmon whose fry overlap most in estuarine marsh areas are chum and chi nook (Congleton et al. 1982; Levy and Northcote 1982). However, detrimental interaction between these two species is limited by differences in migration timing, with chum preceding chinook in the marsh, and by different marsh with chum fry residency periods, spending a relatively short time in the estuaries compared to chinook fry (Levy and Northcote 1982). Beacham and Starr (1982) indicated that the return to escapement ratio for oddnumbered brood years of chum salnon was positively statistically correwith (1) early downstream lated migration of chum salmon fry relative to that of pink salmon fry and (2) with increased spawning escapement of chum salmon relative to that of pink sal non.

Kaczynski Gerke and (1972)reported that juvenile pink and chum salnon school together in Puget Sound in odd-numbered years, and found no significant difference in the size of prey chosen by the two species. LeBrasseur et al. (1969) found that pink and chum salmon in the Fraser River Estuary consumed varying amounts of the same food items. In neither of these studies was there any evidence that competition for any food items limited growth or survival of either salmonid species.

Puget Sound offers a unique opportunity to examine interactions between chum and pink salmon because the pink salmon are not present during even-numbered years. If Puget Sound is considered as a whole, approximately half as many wild chum salmon return

in the odd-numbered years when pink salmon are present (Ames 1981); the wild chum salnon runs average 808,000 fish in even-numbered years compared to 374,000 fish in odd-numbered years (J. Anes, pers. comm.). The early estuarine life of these two salmon species seems to be the critical period of their interaction, since it is well known that no interaction occurs in freshwater and open-ocean interaction is minimal (Ames 1981). In Puget Sound. it has been shown that as the number of wild pink salmon recruits (down stream migrants) per spawning adult increases, there is a significantly correlated decline in escapement of wild chum salnon (Figure 4). A similar impact on chum salmon by pink salmon has been observed by Beacham and Starr (1982), in which a decline in downstream migration of chum fry and spawning of chum salnon was correlated to an increased number of pink salmon.

#### ENVIRONMENTAL REQUIREMENTS

#### Temperature

According to Manzer et al. (1965) chum salnon at sea are found through a

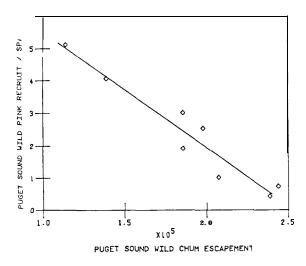

Figure 4. Relationship of Puget Sound wild chum salnon escapement to Puget Sound wild pink salnon recruits (young downstream migrants) per spawner (after Ames 1981).

wide range of temperatures from 3 to 22 °C. An optimum temperature 10.1 °C with a range of 8.3 to 15.6 °C has been noted for successful upstream migration of adult chum salmon (Bell 1973; Reiser and Bjornn 1979). Spawning temperatures for chum salnon range between 7.2 and 12.8 °C (Reiser and Bjornn 1979). Stream water temperatures of 0 to 15 °C have been noted for chum salmon incubation, although eggs are thought to survive best at 4.4 to **14** °C (Schroder **1973**; Koski Reiser and Bjornn 1979). Egg survival was highest at 8 °C and anong eggs produced by the smallest (Beacham and Murray 1985). (1952) observed chum salmon fry to prefer temperatures of 12 to 14 °C and to avoid temperatures above 15  $^{\circ}$ C. The upper lethal temperature for young chum salmon has been documented at 23.8 °C and the lower lethal temperature at 0 °C (Brett 1952).

### **Salinity**

water can interfere fertilization of the eggs of salmon spawni ng in or near the intertidal mari ne zone (Rockwell 1956). After absorption of the yolk sac, chum salmon can tolerate fullstrength seawater (Weishart 1978). Hoar. (1976) reported that chum salmon appear 1 th have a physiological requirement for seawater 3 to 4 months after energence if normal development is to proceed. Shepard experimentally showed that chum salmon fry would preferentially choose a seawater run over a freshwater run, choose a regardless of flow strength.

# Dissolved Oxygen

Reiser and Bjornn (1979) reported that low concentrations of dissolved oxygen can reduce swimming performance by adult salmonids and sometimes causes migration to cease. Daykin (1965) reported that the rate of supply of dissolved oxygen is more important to the eggs or alevins than the actual concentration. Water saturated with

oxygen may be regarded as an optimal condi ti on for and alevins eggs although concentration of oxygen in depends freshwater largely on temperature (Alderdice et al. 1958). Critical oxygen levels (above which respiratory rates are unnodified by oxygen availability) range from 1 ppm in early embryonic stages to 7 ppm shortly before hatching (Alderice et al. 1958). Wickett (1954) linked high mortality of eggs with low dissolved oxygen and low water velocity. and Bjornn (1979) summarized the effect of oxygen concentration on egg development as follows: (1) fry reared at low oxygen levels were smaller and weaker than those reared at higher concentrations; concentrations reduced oxygen lengthened incubation peri ods caused prenature hatching.

## **Substrate**

suitability of substrate The particles of a particular size depends mostly on fish size and may vary from 1.3 to 10.2 cm for spawning chum salnon (Reiser and Bjornn 1979). is a positive correlation between highly permeable gravel substrate and survival of chum salmon eggs (Wickett Dill and Northcote (1970) reported that chum salmon survival to energence approaches 100% in large gravel (5.1 to 10.2 cm), but is only 31% in small gravel (< 5.0 cm), and they concluded that the lower survival was due to entrapment of the fry by Rukhlov (1969) reported a positive relationship between increasing sand content and egg nortality, and considered sedimentation during incubation period as a major source of egg mortality. The size and shape of substrate particles are directly correlated with the incubation time of eggs and the normal development of alevins (Hale 1981).

#### Water Depth

Water depth must be adequate to enable adult salmon to migrate  $$\rm up\mbox{-}$ 

stream to spawn. Extremely low water levels, especially when coupled with barriers, can make streams impassable to spawning adults. The average water depth over chum salmon redds in Oregon streams was 30 cm, while in Washington streams it ranged from 23 to 46 cm (Smith 1973).

## Water Velocity

Low stream velocity and hi gh stream velocity can both adversely affect chum sal non (Wickett 1958; and Bjornn 1979). Reiser Spawni ng adult chum salmon use water with velocities varying between 46 and 101 cm/sec (Smith 1973; Reiser and Bjornn Tautz and Grott (1975) reported that chum salmon chose to spawn in an area of accelerating water flow, such that encountered at pool-riffle Stream flow regulates interchanges. the amount of spawning area available (Reiser and Bjornn 1979): increased flow covers more gravel, thus making sui table spawni ng substrate available; but when the flow reaches a velocity that causes erosion of the substrate. sui table spawning is decreased.

Wickett (1958) showed a significant relationship between spawners and the amount of rainfall in July and August. This association can be fairly well depicted by an inverted parabola, suggesting that increased rainfall is beneficial up to a point (approximately 20 inches), but too much rainfall is detrimental to spawning.

Pacific . salmon requi re eggs velocities of running water that keep water well-oxygenated, the tect the substrate from freezing temeratures. and remove waste metabolites such as carbon dioxide (Hale Adequate water velocity is necessary to prevent siltation buildup in the gravel substrate, which is a major cause of egg and alevin mortality (Reiser and Bjornn 1979; Duker and Colley 1981; Hale 1981).

# Turbi di ty

Turbidity that leads to sedimentation has been reported to be an important cause of egg mortality (McNeil 1962; Bakkala 1970). High turbidity of the water can be inhibiting to adults attempting upstream migration (Reiser and Bjornn 1979; Hale 1981). Suspended sediment

concentrations of 15.8 to 54.9 g/l were found to be the 96-h  $LD_{50}$  value for Puget Sound juvenile chum salmon (Bakkala 1970), indicating that chum salmon tolerate very high concentrations of suspended sediments. Suspended sediment is much more detrimental to eggs, juvenile stages, and invertebrates in the diet of the young fish than it is to adult fish.

15. Abstract (Limit: 200 words)

Species profiles are literature summaries of the taxonomy, morphology, range, life history, and environmental requirements of coastal aquatic species. They are designed to assist in environmental impact assessment. Chum salmon are anadromous fish found throughout a large part of the North Pacific Ocean and are the most widely distributed of all the Pacific salmon. Adults return to spawn in late summer and fall. Young fish migrate downstream quickly and rear in estuaries. Chum salmon mature later in life in more northerly water: in Alaska and British Columbia at age 4 to age 5, in Washington and Oregon at age 3 to age 4. Fish from larger river systems grow to the largest size. The major commercial fishery is centered in Southeast Alaska and British Columbia. Harvest has increased in Washington to 1,150,000 fish annually due to increased hatchery production, with Hood Canal rivers accounting for 25% of all Washington fish. In odd-numbered years, the adult return-to-escapement ratio in any given river system is positively statistically correlated with increased spawning escapement of chum salmon relative to that of pink salmon.

OPTIONAL FORM 272 (4-7 (Formerly NTIS-35) Department of Commerce As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in island territories under U.S. administration.
